

ABSTRACT

Parallax scrolling is a progressively used tool in web design. By allowing the background graphics to move slower than the foreground photos, this scrolling method gives a page the illusion of depth. Apart from letting users participate with a website, supporters of parallax scrolling assert it enhances user experience.

Researchers credit this good user experience on the fulfillment of the following standards: usability, contentment, enjoyment, fun, and visual appeal. We reasoned that parallax scrolling would favorably affect each of these five criteria as well as the user experience generally.

Eighty-six people from a big Midwestern institution took part in the study. One group—N = 43— interacted with the parallax scrolling page,

The second group, N = 43, engaged with the non-parallactic scrolling page instead. T-test for different samples.

revealed significant variations in the views of the two groups on expected pleasure. The participants thought that the

The non-parallax scrolling webpage lacked the appeal of the parallax scrolling one. Moreover augmenting the outcome of the research are

proved that parallax scrolling works better in hedonic and attractive surroundings. Two of the participants had motion sickness and reported major usability problems while using the parallax scrolling website, notwithstanding these advantages. This potential harm to users thus raises some ethical issues for UX designers and web developers considering whether to apply parallax scrolling.
